JUL 0 2 2008

Atty Dkt No.: 2003P16618 US
Serial No.: 10/814,407**AMENDMENTS TO THE CLAIMS**

This listing of claims will replace all prior versions, and listings, of claims in the application:

Listing of Claims:

1. (currently amended) A method for managing traffic on a switching system comprising:

determining a system traffic level indicating the load level of system traffic across a system at a given time;

correlating the determined traffic level with a predetermined level of available service functionality; and

establishing an available services list.

2. (original) The method of claim 1, further comprising:

receiving a service request from a requesting end point;

determining whether the service request is one of the available services on said available services list;

generating a service availability message for the requested service; and
transmitting the service availability message to the requesting end point.

3. (currently amended) The method of claim 1, wherein the given time for the system traffic determination is periodic.

4. (currently amended) The method of claim 1, wherein said system further includes a server, the system traffic determination is executed by said a central server.

5. (currently amended) The method of claim 2, wherein the system traffic may include traffic from point to point connections and conference connections and determining the system traffic level determination is initiated upon receipt of the service request.

Amendment in response to
Office 3, 2008 Action

Atty Dkt No.: 2003P16618 US
Serial No.: 10/814,407

6. (currently amended) The method of claim 1, said system including a plurality of system end points communicating with each other, said method further comprising creating a correlation table comprising data fields including an upper traffic level limit and a lower traffic level limit and a list of services provided to an end point endpoint when the determined traffic level falls within the upper and lower traffic limits.

7. (original) The method of claim 6, wherein the correlation table provides weighted services availability.

8. (currently amended) The method of claim 6, wherein each of said plurality of system end points includes a communications device and the correlation table includes weighted services that are distributed according to a service class determined by the amount of bandwidth necessary to implement a service.

9. (currently amended) The method of claim 8, wherein the service class includes voice-based communication services, the voice-based communication services including traffic point to point voice calls and teleconferences.

10. (currently amended original) The method of claim 8, wherein the service class includes video-based communication services, the video-based communication services including traffic point to point video calls and video conferences.

11. (original) The method of claim 2, wherein the service availability message notifies the end point that the requested service is available based on the traffic level determination.

12. (currently amended) The method of claim 2, wherein the service availability message notifies the end point endpoint that the requested service is unavailable based on the traffic level determination.

13. (original) The method of claim 12, wherein when the service is unavailable, the end point informs a user that the requested service is temporarily unavailable.

Amendment in response to
April 3, 2008 Office Action

Atty Dkt No.: 2003P16618 US
Serial No.: 10/814,407

14. (original) The method of claim 12, wherein when the service is unavailable, a central server creates an entry on a negative request queue corresponding to the service request.

15. (currently amended) The method of claim 14, wherein the entry on the negative request queue includes a field identifying the service requesting end point endpoint.

16. (original) The method of claim 14, wherein the entry on the negative request queue includes a field indicating the type of service requested.

17. (original) The method of claim 14, further comprising transmitting a status update message from the central server to the end point when the requested service becomes available.

18. (original) The method of claim 14, further comprising forwarding the service request to a second end point when the requested service becomes available.

19. (original) The method of claim 2, further comprising the requesting end point establishing a connection through the switching system to provide a user with the service requested.

20. (currently amended) A method for conducting traffic management on a network comprising:

creating a list of available system services;

updating the list of available system services based on a network traffic measurement and network performance parameters associated with system services,
said measurement measuring the level of traffic on a network of a plurality of network end points communicating with each other; and

selectively suppressing network device service requests based on whether a requested service corresponds to an entry on the list of available system services.

Amendment in response to

Atty Dkt No.: 2003P16618 US
Serial No.: 10/814,407

21. (currently amended) The method of claim 20, wherein a network [[user]] end point transmits the network device service request.

22. (currently amended) The method of claim 20, wherein a network end point receives a service availability message indicating whether the requested service will be provided.

23. (currently amended) The method of claim 22, wherein when the network end point receives a service availability message indicating the requested service will not be provided, the network end point receives a second message when the requested service becomes available.

24. (original) The method of claim 20, wherein the network performance parameters include a list of system defined services and associated bandwidth capacity levels.

25. (currently amended) An apparatus for managing traffic on a switching system comprising:

[[a]] traffic determining means for determining the [[a]] level of system traffic across a system at a given time;

[[a]] correlation means for correlating the determined traffic level with a predetermined level of available service functionality; and

[[an]] establishing means for establishing an available services list.

26. (currently amended) The apparatus of claim 25, further comprising:

[[a]] receiving means for receiving a service request from a requesting end point;

[[a]] available services determining means for determining whether the service request is one of the available services on said available services list;

[[a]] generating means for generating a service availability message for the requested service.

Amendment in response to
April 3, 2008 Office Action

Atty Dkt No.: 2003P16618 US
Serial No.: 10/814,407

27. (currently amended) The apparatus of claim 26, further comprising:

[[a]] transmitting means for transmitting the service availability message to the requesting end point.

28. (original) The apparatus of claim 27, wherein the service availability message notifies the end point that the requested service is unavailable;

a central server creates an entry on a negative request queue corresponding to the service request; and

the central server notifies the end point when the requested service becomes available.

29. (currently amended) An apparatus for conducting traffic management on a network comprising:

[[a]] creating means for creating a list of available system services for network end points;

[[an]] updating means for updating the list of available system services based on a network traffic measurement of the network traffic load at a given time and network performance parameters associated with system services; and

[[a]] suppressing means for selectively suppressing network device service requests based on whether the requested service corresponds to an entry on the list of available system services.

30. (currently amended) The apparatus of claim 29, wherein the updated list of available services indicates which services are available to end points on the network based on the network traffic measurement, the apparatus further comprising:

[[a]] transmitting means for transmitting first message to a requesting network device that the requested service should be suppressed; and

said transmitting means subsequently transmits a second message to the network device when the requested service becomes available.
